Definition

- A group G is **nilpotent** of class c if

$$G = \Gamma_1(G) \geq \Gamma_2(G) \geq \cdots \Gamma_c(G) > \Gamma_{c+1}(G) = \{1\}$$

where $\Gamma_{i+1} = [\Gamma_i, G] = \langle x^{-1}g^{-1}xg \text{ for } x \in \Gamma_i, g \in G \rangle$.

- τ -group** = finitely generated torsion-free nilpotent group.

Examples:

- unitriangular matrices $UT_n(\mathbb{Z})$
(upper triangular and diagonal entries 1)
- Heisenberg groups
- free nilpotent groups
 $F_{k,c} = \langle a_1, \dots, a_k \mid [x_1, \dots, x_{c+1}] = 1 \text{ for } x_1, \dots, x_{c+1} \in F_{k,c} \rangle$
where $([x_1, \dots, x_{c+1}] = [[x_1, \dots, x_c], x_{c+1}])$
- $\langle a, b, c, d, e \mid [a, b] = [b, c] = d^2e, [a, c] = e^3,$
 $[e, x] = [d, x] = 1 \forall x \rangle$

Embeddings of τ -Groups

Theorem (Jennings 1955)

Every τ -group can be embedded into $UT_N(\mathbb{Z})$ for some $N \in \mathbb{N}$.

The embedding is given by the G -action on $\mathbb{Q}G/I^{c+1}$ where $I = \left\{ \sum_g \alpha_g g \mid \sum_g \alpha_g = 0 \right\}$ is the augmentation ideal.

Nickels seems to be the “best” for doing actual computations.

Why embeddings into matrices are useful:

- lot known about matrices – linear algebra
- computations are easy (word problem in Logspace,...)
- basic building block for embedding polycyclic groups: interesting for cryptographic purposes

Why embeddings into matrices are useful:

Desired properties properties of embeddings:

- small dimension (little overhead when doing computations)
- easy to compute
- undistorted (geometry is preserved)
- preserves conjugacy etc.

Mal'cev coordinates

Let G be a τ -group with Mal'cev basis $(a_1, \dots, a_n) = \vec{a}$.

- Each $g \in G$ has a **unique** normal form

$$g = a_1^{x_1} \cdots a_n^{x_n} =: \vec{a}^{\vec{x}}$$

Let $f \in \mathbb{Q}[x_1, \dots, x_n]$, then the G -submodule $M = \text{span}(f^G)$ of $(\mathbb{Q}G)^$ generated by f is finite-dimensional as a \mathbb{Q} -vector space.*

Nickel's Embedding

Let t_i be the i 'th coordinate function:

$$\begin{aligned} t_i : G &\rightarrow \mathbb{Z} \\ a_1^{x_1} \cdots a_n^{x_n} &\mapsto x_i \end{aligned}$$

Well-def. since each $g \in G$ can be written uniquely as $a_1^{x_1} \cdots a_n^{x_n}$.

$$t_i \in \mathbb{Q}[x_1, \dots, x_n] \subseteq \{f : \mathbb{Z}^n \rightarrow \mathbb{Q}\} = \{f : G \rightarrow \mathbb{Q}\} = (\mathbb{Q}G)^*$$

Lemma (Nickel, 2006)

Let $f \in \mathbb{Q}[x_1, \dots, x_n]$, then the G -submodule $M = \text{span}(f^G)$ of $(\mathbb{Q}G)^$ generated by f is finite-dimensional as a \mathbb{Q} -vector space.*

Lemma (Nickel, 2006)

The submodule $M = \text{span}(\{t_1, \dots, t_n\}^G)$ of $(\mathbb{Q}G)^$ generated by t_1, \dots, t_n is a finite dimensional faithful G -module.*

Theorem

Let G be of nilpotency class c and $k = \text{rk}(G/[G, G])$. Then Nickel's embedding has dimension at most

$$\sum_{i=0}^{c-1} k^i + \text{rk}(\Gamma_c(G)) < 2k^c.$$

Moreover, it has never larger dimension than Jennings' embedding.

Theorem (Lo, Ostheimer, 1999)

Jennings' embedding of $F_{k,c}$ has dimension exactly $\sum_{i=0}^c k^i$.

Let G and H be two τ -groups with Mal'cev bases (a_1, \dots, a_m) and (a_{m+1}, \dots, a_n) .

Let G and H be two τ -groups with Mal'cev bases (a_1, \dots, a_m) and (a_{m+1}, \dots, a_n) .

Then $(a_1, \dots, a_m, a_{m+1}, \dots, a_n)$ is a Mal'cev basis of $G \times H$.

Let G and H be two τ -groups with Mal'cev bases (a_1, \dots, a_m) and (a_{m+1}, \dots, a_n) .

Then $(a_1, \dots, a_m, a_{m+1}, \dots, a_n)$ is a Mal'cev basis of $G \times H$.

Proposition

Let M (resp. N) be the dimension of Nickel's embedding of G (resp. H) into $UT_M(\mathbb{Z})$ (resp. $UT_N(\mathbb{Z})$). Then Nickel's embedding of $G \times H$ has dimension

$$M + N - 1.$$

Example

- $G = \mathbb{Z}^k$
- $H = \mathbb{Z}^c \rtimes_{\varphi} \mathbb{Z}$ where the action \mathbb{Z} on \mathbb{Z}^c is defined by the matrix

$$\begin{pmatrix} 1 & 1 & 0 & \cdots & 0 \\ & 1 & 1 & \ddots & \vdots \\ & & 1 & \ddots & 0 \\ & 0 & & \ddots & 1 \\ & & & & 1 \end{pmatrix}$$

Jennings' embedding has the following sizes

- for G : $k + 1$
- for H : $2^{\mathcal{O}(\sqrt{c})}$
- for $G \times H$: greater than $\binom{k+c}{c}$ (for $k = c$ this is $\approx 4^k / \sqrt{k}$).
